Benchmark Functions for CEC’2013 Special Session and Competition on Niching Methods for Multimodal Function Optimization

Xiaodong Li, Andries Engelbrecht, Michael G. Epitropakis

Evolutionary Algorithms (EAs) in their original forms are usually designed for locating a single global solution. These algorithms typically converge to a single solution because of the global selection scheme used. Nevertheless, many real-world problems are “multimodal” by nature, i.e., multiple satisfactory solutions exist. It may be desirable to locate many such satisfactory solutions so that a decision maker can choose one that is most proper in his/her problem domain. Numerous techniques have been developed in the past for locating multiple optima (global or local). These techniques are commonly referred to as “niching” methods. A niching method can be incorporated into a standard EA to promote and maintain formation of multiple stable subpopulations within a single population, with an aim to locate multiple globally optimal or suboptimal solutions. Many niching methods have been developed in the past, including crowding [1], fitness sharing [2], deterministic crowding [3], derating [4], restricted tournament selection [5], parallelization [6], stretching and deflation [7], clustering [8], clearing [9], and speciation [10], etc.

Although these niching methods have been around for many years, further advances in this area have been hindered by several obstacles: most studies focus on very low dimensional multimodal problems (2 or 3 dimensions), therefore it is difficult to assess these methods’ scalability to high dimensions; some niching methods introduce new parameters which are difficult to set, making these methods difficult to use; different benchmark test functions or different variants of the same functions are used, hence comparing the performance of different niching methods is difficult.

We believe it is now time to adopt a unifying framework for evaluating niching methods, so that further advance in this area can be made with ease. In this technical report, we put together 20 benchmark test functions (including several identical functions with different dimension sizes), with different characteristics, for evaluating niching algorithms. The first 10 benchmark functions are simple, well known and widely used functions, largely based on some recent studies on niching [11], [12], [13]. The remaining benchmark functions are more complex and follow the paradigm of composition functions defined in the IEEE CEC 2005 special session on real-parameter optimization [14].

Several of the test functions included here are scalable to dimension, and the number of global optima can be adjusted freely by the user. Performance measures are also defined and suggested here for comparing different niching methods. The source codes of the benchmark test functions are made available in Matlab, Java and C++ source codes. The competition files can be downloaded from the CEC’2013 special session on niching methods website1.

In the following sections, we will describe the mathematical formula and properties of the included multimodal benchmark test functions, evaluation criteria, and the ranking method for entries submitted to this competition.

I. Summary of Test Functions

This benchmark set includes the following 20 multimodal test functions:

- $F_1$: Five-Uneven-Peak Trap (1D)
- $F_2$: Equal Maxima (1D)
- $F_3$: Uneven Decreasing Maxima (1D)
- $F_4$: Himmelblau (2D)
- $F_5$: Six-Hump Camel Back (2D)
- $F_6$: Shubert (2D, 3D)
- $F_7$: Vincent (2D, 3D)
- $F_8$: Modified Rastrigin - All Global Optima (2D)
- $F_9$: Composition Function 1 (2D)
- $F_{10}$: Composition Function 2 (2D)
- $F_{11}$: Composition Function 3 (2D, 3D, 5D, 10D)
- $F_{12}$: Composition Function 4 (3D, 5D, 10D, 20D)

These multimodal test functions have following properties:

- All test functions are formulated as maximization problems;
- $F_1$, $F_2$ and $F_3$ are simple 1D multimodal functions;
- $F_4$ and $F_5$ are simple 2D multimodal functions. These functions are not scalable;
- $F_6$ to $F_8$ are scalable multimodal functions. The number of global optima for $F_6$ and $F_7$ are determined by the dimension $D$. However, for $F_8$, the number of global optima is independent from $D$, therefore can be controlled by the user.
- $F_9$ to $F_{12}$ are scalable multimodal functions constructed by several basic functions with different properties. $F_9$

1 URL: http://goanna.cs.rmit.edu.au/~xiaodong/cec13-niching/
and $F_{10}$ are separable, and non-symmetric, while $F_{11}$ and $F_{12}$ are non-separable, non-symmetric complex multimodal functions. The number of global optima in all composition functions is independent from $D$, therefore can be controlled by the user.

II. DEFINITIONS OF THE TEST FUNCTIONS

A. $F_1$: Five-Uneven-Peak Trap

$$F_1(x) = \begin{cases} 
80(2.5 - x) & \text{for } 0 \leq x < 2.5, \\
64(x - 2.5) & \text{for } 2.5 \leq x < 5.0, \\
64(7.5 - x) & \text{for } 5.0 \leq x < 7.5, \\
28(x - 7.5) & \text{for } 7.5 \leq x < 12.5, \\
28(17.5 - x) & \text{for } 12.5 \leq x < 17.5, \\
32(x - 17.5) & \text{for } 17.5 \leq x < 22.5, \\
32(27.5 - x) & \text{for } 22.5 \leq x < 27.5, \\
80(x - 27.5) & \text{for } 27.5 \leq x \leq 30.
\end{cases}$$

Properties:
- Variable ranges: $x \in [0, 30]$;
- No. of global optima: 2;
- No. of local optima: 3.

This function was originally proposed in [10]. See Fig. 1.

B. $F_2$: Equal Maxima

$$F_2(x) = \sin^6(5\pi x).$$

Properties:
- Variable ranges: $x \in [0, 1]$;
- No. of global optima: 5;
- No. of local optima: 0;

This function was originally proposed in [15]. See Fig. 2.

C. $F_3$: Uneven Decreasing Maxima

$$F_3(x) = \exp\left(-2\log(2)\left(\frac{x - 0.08}{0.854}\right)^2\right)\sin^6(5\pi(x^{3/4} - 0.05)).$$

D. $F_4$: Himmelblau

$$F_4(x, y) = 200 - (x^2 + y - 11)^2 - (x + y^2 - 7)^2.$$  

Properties:
- Variable ranges: $x, y \in [-6, 6]$;
- No. of global optima: 4;
- No. of local optima: 0;

This is an inverted version of Himmelblau function [15]. It has 4 global optima with 2 closer to each other than the other 2. There are no local optima, as shown in Fig. 4.

E. $F_5$: Six-Hump Camel Back

$$F_5(x, y) = -4[(4 - 2.1x^2 + \frac{x^4}{3})x^2 + xy + (4y^2 - 4)y^2].$$
Fig. 4. Himmelblau.

**Properties:**
- Variable ranges: $x \in [-1.9, 1.9]; y \in [-1.1, 1.1]$;
- No. of global optima: 2;
- No. of local optima: 2;

This function was originally proposed in [16]. The function has 2 global optima as well as 2 local optima. See Fig. 5.

Fig. 5. Six-Hump Camel Back.

**F. F_6: Shubert**

$$F_6(\vec{x}) = -\prod_{i=1}^{D} \sum_{j=1}^{5} j \cos((j + 1)x_i + j).$$

**Properties:**
- Variable ranges: $x_i \in [-10, 10]^D, i = 1, 2, \ldots, D$;
- No. of global optima: $D \cdot 3^D$;
- No. of local optima: many;

This function is an inverted version of the Shubert function [16], [10], where there are $n3^D$ global optima unevenly distributed. These global optima are divided into $3^D$ groups, with each group having $D$ global optima being close to each other. Fig. 6 shows an example of the Shubert 2D function, where there are 18 global optima in 9 pairs (each with an objective function value of 186.73), with each pair very close to each other, but the distance between any pair is much greater. There are in total 760 global and local optima.

Fig. 6. Shubert 2D function.

**G. F_7: Vincent**

$$F_7(\vec{x}) = \frac{1}{D} \sum_{i=1}^{D} \sin(10\log(x_i))$$

**Properties:**
- Variable range: $x_i \in [0.25, 10]^D, i = 1, 2, \ldots, D$;
- No. of global optima: $6^D$;
- No. of local optima: 0;

This is an inverted version of the Vincent function [17], which has $6^D$ global optima (each with an objective function value of 1.0), but unlike the regular distances between global optima in $F_6$, in Vincent function the global optima have vastly different spacing between them. In addition, the Vincent function has no local optima. Fig. 7 shows an example of the Vincent 2D function.

Fig. 7. Vincent 2D function.
\( F_9(\vec{x}) = -\sum_{i=1}^{D} (10 + 9\cos(2\pi k_ix_i)) \).

**Properties:**

- Variable ranges: \( x_i \in [0,1]^D, i = 1, 2, \ldots, D \);
- No. of global optima: \( \prod_{i=1}^{D} k_i \);
- No. of local optima: 0;

This is a modified Rastrigin function according to [13]. The total number of global optima is \( M = \prod_{i=1}^{D} k_i \). In [13], a problem instance \( D = 16 \) was used, with the following setting: \( k_i = 1 \), for \( i = 1 - 3, 5 - 7, 9 - 11, 13 - 15 \), and \( k_4 = 2, k_7 = 2, k_9 = 3, k_{16} = 4 \). In this case, there are 48 evenly distributed global optima, each having an identical objective value of \( f = 16 \). Fig. 8 provides a problem instance of this function in 2D (where \( D = 2, k_1 = 3, k_2 = 4 \)), in which case the total number of optima is 12.

1. Composition functions

In this section, we first describe the general framework for constructing multimodal composition functions with several global optima, then present the new composition functions used in this technical report.

More specifically, a \( D \)-dimensional, composition function \( CF_j : A_D \subset \mathbb{R}^D \rightarrow \mathbb{R} \) can be generally constructed as a weighted aggregation of \( n \) basic functions \( f_i : A_D \subset \mathbb{R}^D \rightarrow \mathbb{R} \). Each basic function is shifted to a new position inside the optimization space \( A_D \) and can be either rotated through a linear transformation matrix or used as is. Thus, a composition function \( CF_j \) is calculated according the following equation:

\[
CF_j(\vec{x}) = \sum_{i=1}^{n} w_i \left( \hat{f}_i(\vec{x} - \vec{a}_i)/\lambda_i \cdot M_i \right) + f_{bias}^i,
\]

where \( n \) is the number of basic functions used to construct the composition function, \( \hat{f}_i \) denotes a normalization of the \( i \)-th basic function, \( i \in \{1, 2, \ldots, n\} \), \( w_i \) is the corresponding weight, \( \vec{a}_i \) is the new shifted optimum of each \( \hat{f}_i \), \( M_i \) is the linear transformation (rotation) matrix of each \( \hat{f}_i \), and \( \lambda_i \) is a parameter which is used to stretch (\( \lambda_i > 1 \)) or compress (\( \lambda_i < 1 \)) each \( f_i \) function. The composition function includes two bias parameters \( \text{bias}_i \) and \( f_{bias}^i \). The former defines a function value bias for each basic function and denotes which optimum is the global optimum, while the latter defines a function value bias for the constructed composition function. Here, we set the bias \( \text{bias}_i = 0, \forall i \in \{1, 2, \ldots, n\} \), thus the global optimum of each basic function is a global optimum of the composition function. In addition, we set \( f_{bias}^i = 0 \), as such in each composition function, all global optima have fitness values equal to zero.

The weight \( w_i \) of each basic function can be easily calculated based on the following equations:

\[
w_i = \exp \left( -\frac{\sum_{k=1}^{D} (x_k - o_{i,k})^2}{2D\sigma_i^2} \right),
\]

\[
w_i = \begin{cases} w_i & w_i = \max(w_i) \\ w_i(1 - \max(w_i)^{10}) & \text{otherwise.} \end{cases}
\]

Finally, the weights are normalized according to \( w_i = w_i / \sum_{i=1}^{n} w_i \). The parameter \( \sigma_i \) controls the coverage range of each basic function, with small values to produce a narrow coverage range to the corresponding \( \hat{f}_i \).

The pool of basic functions may include functions with different properties, characteristics and heights. As such to have a better mixture of the basic functions a normalization procedure is incorporated. The normalized function \( \hat{f}_i \), can be defined as: \( \hat{f}_i(\cdot) = C f_i(\cdot)/f_i^\text{max} \), where \( C \) is a predefined constant (\( C = 2000 \)) and \( f_i^\text{max} \) is estimated using: \( f_i^\text{max} = f_i((x^*/\lambda_i) M_i) \), with \( x^* = [5, 5, \ldots, 5] \).

The pool of basic functions that we have used to construct the composition functions includes the following:

- Sphere function:

\[
\hat{f}_S(\vec{x}) = \sum_{i=1}^{D} x_i^2.
\]

- Grienwank’s function:

\[
f_G(\vec{x}) = \sum_{i=1}^{D} \frac{x_i^2}{4000} - \prod_{i=1}^{D} \cos \left( \frac{x_i}{\sqrt{i}} \right) + 1.
\]

- Rastrigin’s function:

\[
f_R(\vec{x}) = \sum_{i=1}^{D} (x_i^2 - 10 \cos(2\pi x_i) + 10).
\]

- Weierstrass function:

\[
f_W(\vec{x}) = \sum_{i=1}^{D} \left( \sum_{k=0}^{\text{kmax}} \alpha^k \cos \left( 2\pi \beta^k (x_i + 0.5) \right) - D \sum_{k=0}^{\text{kmax}} \alpha^k \cos \left( 2\pi \beta^k (0.5) \right) \right),
\]

where \( \alpha = 0.5, \beta = 3 \), and \( \text{kmax} = 20 \).
Fig. 9 shows the 2D version of CF1.

The composition function is constructed based on the following parameter settings:

- \( \sigma_i = 1, \forall i \in \{1, 2, \ldots, n\} \)
- \( \lambda = [1, 1, 10, 10, 1/10, 1/10, 1/7, 1/7] \)
- \( M_i \) are identity matrices \( \forall i \in \{1, 2, \ldots, n\} \)

Fig. 9 shows the 2D version of CF1.

**Properties:**
- Multi-modal,
- Shifted,
- Non-Rotated,
- Non-symmetric,
- Separable near the global optima,
- Scalable,
- Numerous local optima,
- Different function’s properties are mixed together,
- Sphere Functions give two flat areas for the function,
- In the optimization box \( A_D = [-5, 5]^D \), there are six global optima \( x^*_i = o_i, i \in \{1, 2, \ldots, n\} \) with CF1 \( (x^*_i) = 0, \forall i \in \{1, 2, \ldots, n\} \).

**Note on the implementation:** The implementation of the composition functions has been mostly based on the source code of the IEEE CEC 2005 competition on real-parameter optimization [14]. However, the source code has been re-implemented from scratch in a simplified and scalable way. It has to be noted that, similar implementation of composition functions with multiple global optima was proposed in [18]. However, our implementation of the composition functions are different in many ways: new structures, parameters, rotation matrices, and shifted optima positions.

**J. F5 : Composition Function 1**

Composition Function 1 (CF1) is constructed based on six basic functions \( (n = 6) \), thus it has six global optima in the optimization box \( A_D = [-5, 5]^D \). The basic functions used here include the following:

- \( f_1 - f_2 \) : Griewank’s function,
- \( f_3 - f_4 \) : Weierstrass function, and
- \( f_5 - f_6 \) : Sphere function.

The composition function is constructed based on the following parameter settings:

- \( \sigma_i = 1, \forall i \in \{1, 2, \ldots, n\} \)
- \( \lambda = [1, 1, 10, 10, 1/10, 1/10, 1/7, 1/7] \)
- \( M_i \) are identity matrices \( \forall i \in \{1, 2, \ldots, n\} \)

Fig. 9 shows the 2D version of CF1.

**Properties:**
- Multi-modal,
- Shifted,
- Non-Rotated,
- Non-symmetric,
- Separable near the global optima,
- Scalable,
- Numerous local optima,
- Different function’s properties are mixed together,
- Sphere Functions give two flat areas for the function,
- In the optimization box \( A_D = [-5, 5]^D \), there are six global optima \( x^*_i = o_i, i \in \{1, 2, \ldots, n\} \) with CF1 \( (x^*_i) = 0, \forall i \in \{1, 2, \ldots, n\} \).

**K. F10 : Composition Function 2**

Composition Function 2 (CF2) is constructed based on eight basic functions \( (n = 8) \), thus it has eight global optima in the optimization box \( A_D = [-5, 5]^D \). The basic functions used here include the following:

- \( f_1 - f_2 \) : Rastrigin’s function,
- \( f_3 - f_4 \) : Weierstrass function,
- \( f_5 - f_6 \) : Griewank’s function, and
- \( f_7 - f_8 \) : Sphere function.

The composition function is constructed based on the following parameter settings:

- \( \sigma_i = 1, \forall i \in \{1, 2, \ldots, n\} \)
- \( \lambda = [1, 1, 10, 10, 1/10, 1/10, 1/7, 1/7] \)
- \( M_i \) are identity matrices \( \forall i \in \{1, 2, \ldots, n\} \)

Fig. 10 shows the 2D version of CF2.

**Properties:**
- Multi-modal,
- Shifted,
- Non-Rotated,
- Non-symmetric,
- Separable near the global optima,
- Scalable,
- Numerous local optima,
- Different function’s properties are mixed together,
- In the optimization box \( \mathcal{A}_D = [-5, 5]^D \), there are eight global optima \( x_i^* = \vec{a}_i, i \in \{1, 2, \ldots, n\} \) with \( \text{CF}_3(x_i^*) = 0, \forall i \in \{1, 2, \ldots, n\} \).

**L. \( F_{11} \): Composition Function 3**

Composition Function 3 (CF3) is constructed based on six basic functions \((n = 6)\), thus it has six global optima in the optimization box \( \mathcal{A}_D = [-5, 5]^D \). The basic functions used here include the following:
- \( f_1 - f_2 \): EF8F2 function,
- \( f_3 - f_4 \): Weierstrass function, and
- \( f_5 - f_6 \): Griewank’s function.

The composition function is constructed based on the following parameter settings:
- \( \vec{\sigma} = [1, 1, 1, 1, 1, 2, 2, 2] \),
- \( \vec{\lambda} = [1/4, 1/10, 2, 1, 2, 5] \),
- \( M_i \) are different linear transformation (rotation) matrices with condition number one.

Fig. 11 shows the 2D version of the CF3.

**M. \( F_{12} \): Composition Function 4**

Composition Function 4 (CF4) is constructed based on eight basic functions \((n = 8)\), thus it has eight global optima in the optimization box \( \mathcal{A}_D = [-5, 5]^D \). The basic functions used here include the following:
- \( f_1 - f_2 \): Rastrigin’s function,
- \( f_3 - f_4 \): EF8F2 function,
- \( f_5 - f_6 \): Weierstrass function, and
- \( f_7 - f_8 \): Griewank’s function.

The composition function is constructed based on the following parameter settings:
- \( \vec{\sigma} = [1, 1, 1, 1, 1, 2, 2, 2] \),
- \( \vec{\lambda} = [4, 1, 4, 1/10, 1/5, 1/10, 1/40] \),
- \( M_i \) are different linear transformation (rotation) matrices with condition number one.

Fig. 12 shows the 2D version of the CF4.

**Fig. 12. Composition Function 4.**

### Properties
- Multi-modal,
- Shifted,
- Rotated,
- Non-symmetric,
- Non-separable,
- Scalable,
- A huge number of local optima,
- Different function’s properties are mixed together,
- In the optimization box \( \mathcal{A}_D = [-5, 5]^D \), there are eight global optima \( x_i^* = \vec{a}_i, i \in \{1, 2, \ldots, n\} \) with \( \text{CF}_4(x_i^*) = 0, \forall i \in \{1, 2, \ldots, n\} \).

### III. Performance Measures

**A. How to determine if all global optima are found?**

Our objective is to compare different niching algorithms’ capability to locate all global optima. To achieve this, first we need to specify a level of accuracy (typically \( 0 < \epsilon \leq 1 \)), a threshold value under which we would consider a global optimum is found. Second, we assume that for each test function, the following information is available:
The number of global optima;
- The fitness of the global optima (or peak height), which is known or can be estimated;
- A niche radius value that can sufficiently distinguish two closest global optima.

This information is required by Algorithm 1 (based on a previously proposed procedure [19]), to determine if a niching algorithm has located all the global optima (Table IV provides an example of how this information is used for performance measures in this competition). Basically, at the end of an optimization run, Algorithm 1 is invoked to check all the individuals on the sorted list $L_{sorted}$, starting from the best-fit individual. In the first iteration, as long as this best-fit individual is within $\epsilon$ distance from the fitness of the global optima $p_h$, it will be added to the solution list $S$ (which is initially empty). In the next iteration, the next best-fit individual from $L_{sorted}$ is first assigned to $p$. We then check if the fitness of $p$ is close enough to that of the global optima (i.e., if $d(ph, fit(p)) \leq \epsilon$). If $p$ is close enough (in other words, $p$ is a potential solution), then next we check if $p$ is within the niche radius $r$ from all the current solutions in the solution list $S$. If it is not, then $p$ is considered as a new solution (i.e., a new global optimum is found), and will be added to $S$. Otherwise $p$ is not considered as a distinct solution, and will be skipped. This process is repeated until all the individuals on $L_{sorted}$ have been checked. It is important to note that Algorithm 1 is only used for performance measurement in determining if a sufficient number of global optima has been found, but not in any part of the optimization procedure.

The output of Algorithm 1 is $S$, a solution list containing all the distinct global optima found. As long as $r$ is set to a value not greater than the distance between 2 closest global optima, individuals on two found global optima would be treated as two different solutions. Since the exact number of global optima is known a priori, we can measure a niching algorithm’s performance in terms of the peak ratio, success rate, and averaged number of evaluations required to achieve a given accuracy $\epsilon$ for locating all global optima over multiple runs. These will be described in the following sections.

### B. Peak ratio and success rate

We use peak ratio (PR) [20] and success rate (SR) as two performance measures, to evaluate the performance of a niching algorithm over multiple runs. Given a fixed maximum number of function evaluations (MaxFEs) and a required accuracy level $\epsilon$, PR measures the average percentage of all known global optima found over multiple runs:

$$PR = \frac{\sum_{i=1}^{NR} NPF_i}{NKP \times NR},$$

where $NPF_i$ denotes the number of global optima found in the end of the $i$-th run, $NKP$ the number of known global optima, and $NR$ the number of runs. SR measures the percentage of successful runs (a successful run is defined as a run where all known global optima are found) out of all runs:

$$SR = \frac{NSR}{NR},$$

where $NSR$ denotes the number of successful runs.

### C. Convergence speed

We measure the convergence speed of a niching algorithm by counting the number of function evaluations (FEs) required to locate all known global optima, at a specified accuracy level $\epsilon$. We calculate the average FEs over multiple runs:

$$AveFEs = \frac{\sum_{i=1}^{NR} FE_i}{NR},$$

where $FE_i$ denotes the number of evaluations used in the $i$-th run. If the algorithm cannot locate all the global optima by the MaxFEs, then MaxFEs is used when calculating the average FEs.

### IV. Experimental Settings

We evaluate niching methods by using a fixed amount of MaxFEs. A user is allowed to use any population size, but only a fixed amount of MaxFEs is allowed to be used as a given computational budget.

### A. Peak ratio and success rate

PR and SR are calculated according to equations (1) and (2). The following parameter settings are used:

- Level of accuracy ($\epsilon$): $\{1.0E-01,1.0E-02, \ldots, 1.0E-05\}$;
- Niche radius ($r$): See Table IV;

---

**Algorithm 1:** The algorithm for determining if all global optima are found.

```
begin
S = ∅;
while not reaching the end of $L_{sorted}$ do
    Get best unprocessed $p \in L_{sorted}$;
    found ← FALSE;
    if $d(ph, fit(p)) \leq \epsilon$ then
        for all $s \in S$ do
            if $d(s, p) \leq r$ then
                found ← TRUE;
                break;
        end
    end
    if not found then
        let $S \leftarrow S \cup \{p\}$;
    end
end
```

[Table IV is referenced here for further details.]
• Initialization: Uniform random initialization within the search space;
• Termination of a run: Terminate when reaching MaxFEs.
• Number of runs: 50.

Note that $\epsilon$ and $r$ are to be used only at the end of a run, for evaluations of the final solutions. Table I shows different MaxFEs used for the 3 ranges of test functions.

### Table I
MAXFEs USED FOR 3 RANGES OF TEST FUNCTIONS.

<table>
<thead>
<tr>
<th>Range of functions</th>
<th>MaxFEs</th>
</tr>
</thead>
<tbody>
<tr>
<td>$F_1$ to $F_5$ (1D or 2D)</td>
<td>5.0E+04</td>
</tr>
<tr>
<td>$F_6$ to $F_{11}$ (2D)</td>
<td>2.0E+05</td>
</tr>
<tr>
<td>$F_6$ to $F_{12}$ (3D or higher)</td>
<td>4.0E+05</td>
</tr>
</tbody>
</table>

For $F_8$ (2D), we set $k_1 = 3$ and $k_2 = 4$, as shown in Fig. 8. Table II shows an example of presenting PR and SR values of a typical niching algorithm. Note that in this example the PR and SR values are calculated based on the results of a baseline model, DE/nrand/1/bin algorithm (see details in a section below).

### B. Convergence speed

Convergence speed is calculated according to equation (3), using the same MaxFEs settings in Table I. The accuracy level $\epsilon$ is set to 1.0E-04. Other parameters are the same as in Table IV. Table V presents the convergence speed results of the DE/nrand/1/bin algorithm.

To further illustrate the behaviour of the niching algorithm, we can record the number of global optima found at different iteration steps of a run. We recommend to use figures to show the mean global optima found averaged over 50 runs, on 5 or 6 different test functions of your choice. We encourage authors to follow a recent paper on niching [21] on how to better present results.

### C. Baseline models

To facilitate easy comparisons for participants in the competition, we use as baseline models two Differential Evolution (DE) niching variants, the recently proposed DE/nrand/1/bin algorithm [21] and the well known Crowding DE/rand/1/bin [20]. DE/nrand/1/bin is a simple DE algorithm which incorporates spatial information about the neighborhood of each potential solution to produce a niching formation. On the other hand, Crowding DE/rand/1/bin produces niching formation by incorporating the crowding technique to maintain a better population diversity and therefore to prevent premature convergence to an optimum. The results of the two baseline models are presented in Tables II, III, and Tables V, VI. Please note that we did not conduct any fine-tuning on the parameters of the baseline algorithms. Instead, we used the following default parameters: population size $NP = 100$, $F = 0.5$, $CR = 0.9$, and the crowding factor equals to the population size $CF = NP$.

### V. Ranking method

We will use peak ratio values in Table II as our key criterion to rank algorithms submitted to this competition. The top algorithm is the one that obtains the best average peak ratio, across all test functions and 5 accuracy levels. If there is a tie, then the algorithm having the lower AveFEs in Table V will be the winner.
